Finish up Gale-Shapley  
Greedy Algorithms  
- Interval Scheduling

# Gale-Shapley Algorithm (1962)

while ( $\exists$  an unmatched university  $U$ ):  
     $C \leftarrow$  next candidate  
    if ( $C$  is unmatched or prefers  $U$ ):  
        match  $C$  to  $U$  (and unmatched  $C$  if necessary)

For each university, maintain a list of candidates in order of preference. By next, mean next in this list.

How many times do we go through the loop?  
Each university can make an offer to each candidate at most once.  
 $\Rightarrow$  At most  $n \cdot n = n^2$ , because there are  $n$  universities and  $n$  candidates.

Can we run out of candidates to make offers to?

Invariant: once a candidate receives an offer, they will have an offer for the rest of the algorithm.

If we reach the end of a candidate list, all candidates must have offers,

$n$  candidates have offers  $\rightarrow n$  universities have offers

What is the cost of each loop iteration?

— Need to find candidate preferences efficiently

# Gale-Shapley Algorithm

while ( $\exists$  an unmatched university  $U$ ):  
 $C \leftarrow$  next candidate  
 if ( $C$  is unmatched or prefers  $U$ ):  
     match  $C$  to  $U$  (and unmatched  $C$  if necessary)

For each university, maintain a list of candidates in order of preference. by next, mean next in this list.

What is the cost of each loop iteration?

— Need to find candidate preferences efficiently

Candidate Preferences

	Cornell	Princeton	Rutgers

Jennifer	2	3	1
Raj	2	3	1

# Gale-Shapley Algorithm

while ( $\exists$  an unmatched university  $U$ ):  
     $C \leftarrow$  next candidate  
    if ( $C$  is unmatched or prefers  $U$ ):  
        match  $C$  to  $U$  (and unmatched  $C$  if necessary)

For each university, maintain a list of candidates in order of preference. by next, mean next in this list.

Is the output stable?

Observation:

Candidates' matches only improve

not an unstable pair  $\rightarrow$  {  
    Case 1:  $c'$  rejected <sup>offer</sup>  
         $\Rightarrow c'$  already had a better  
         $\Rightarrow c'$  prefers  $u'$  to  $u$ . By obs.  
    Case 2:  $c'$  accepted  $u$   
        But then at same point  $c'$  accepts  $u'$   
         $\Rightarrow c'$  prefers  $u'$  to  $u$  By obs.  $\square$

Proof the output is stable:

Let  $c, u'$  be an unmatched pair, and  $u$  be  $c$ 's match and  $c'$  be  $u'$ 's match.  
matches:  $c, u$  and  $c', u'$ .

Suppose  $u$  prefers  $c'$  to  $c$ .  
Then  $u$  made an offer to  $c'$ .

# Greedy Algorithms

A greedy algorithm proceeds in steps, making a locally optimal decision at each step, without ever looking at the future.

Usually easy to come up with greedy algorithms  
but hard to show they solve the problem.  
Whether they work depends on what you optimize.

# Interval Scheduling

Input:  $J_1, J_2, \dots, J_n$

$J_i = (s_i, f_i)$

A subset of intervals is called compatible if no 2 overlap.  
Goal: Find the largest compatible subset. (most jobs)

# Interval Scheduling

## Greedy Algorithms

1. Earliest Start Time (FCFS)  
(not correct)

2. Shortest Job  
(not correct)

3. Exhaustive Search  
(correct, exponential time)

4. Fewest Conflicts  
(not correct)

5. Earliest Finish Time  
(looks promising)

Intuition: Choose the job  
that frees the resource  
as soon as possible.

Running Time of EFT:

Sort all the jobs by finish time.  $O(n \log n)$

Start w/ earliest finishing job  $J_1$ . (Process jobs in EFT order)

Then for  $J_2$ , if  $(s_2 < f_1)$  then discard.

Repeat until we don't discard, then replace  $J_1$ .

Running Time of EFT:

Sort all the jobs by Finish time.  $O(n \log n)$

$O(n)$  {  
     $S = \{J_1\}$   
     $L \leftarrow J_1$   
     $i = 2$   
    while ( $J_i$ ):  
        if ( $s_i \geq f(L)$ ):  
             $S.append(J_i)$   
             $L \leftarrow J_i$   
         $i++$

Finish time

of L doesn't conflict

//  $J_i$  conflicts w/ L

Iterate through each job once.

Total Run Time  
 $O(n \log n)$

Does it produce a largest compatible subset?

Lemma: Let  $S$  be the output of EFT.  
Let  $T$  be any compatible subset.  
Order all jobs in  $S$  and  $T$  by EFT.  
 $\swarrow \quad \searrow$   
 $K_1, \dots, K_{|S|} \quad L_1, \dots, L_{|T|}$

Then  $f(K_i) \leq f(L_i)$  for all  $i$ .

Then  $|S| \geq |T|$  for any  $\dots T$ .
